SOIL SURVEY SUPPLEMENT

SEMINOLE COUNTY FLORIDA

United States Department of Agriculture
Soil Conservation Service

SOIL POTENTIALS AND LIMITATIONS

A

SUPPLEMENT TO THE SOIL SURVEY

SEMINOLE COUNTY, FLORIDA

Prepared by

U.S. Department of Agriculture

Soil Conservation Service

and the

Seminole County Board of County Commissioners

1975

Acknowledgements

Published by the Board of County Commissioners of Seminole County, Florida, as part of the Seminole County Comprehensive Plan in cooperation with the Seminole Soil and Water Conservation District and the University of Florida Experiment Stations.

The publication is the combined work of Robert W. Johnson, James F. Brasfield and Fred S. Merrill of the Soil Conservation Service, and Roger Neiswender and Bill Kercher of the Seminole County Department of County Development.

INTRODUCTION

The Soil Survey Seminole County, Florida was published in 1966. This publication is available from the Soil Conservation Service, the Seminole County Planning Division, or the County Extension Service. It is also available in local libraries. There were 54 mapping units recognized and described in the published soil survey. The published survey contains interpretations for various uses in terms of soil limitations and soil features adversely affecting a particular use.

Since the survey was published, a strong need has developed to interpret the soils in terms of their potential for a particular use. Considering the basic properties of the soil as described in the original publication, each soil has been interpreted in terms of its potential for selected land uses.

This publication is intended to complement, as well as supplement, the published soil survey. It is not intended to replace the published soil survey.

HOW TO USE THIS SUPPLEMENT

This publication complements and supplements the "Soil Survey, Seminole County, Florida" and is designed to be used in conjunction with it.

LOCATING SOILS ON THE MAPS

The soils of Seminole County are mapped on 35 individual map sheets. The maps are located in the back of the published Soil Survey. Each sheet is numbered to correspond with a number on the Index to Map Sheets. This index is located at the front and the back of the map sheets for easy reference. To locate the soil map sheet that includes the specific area in which you are interested, refer to the Index to Map Sheets.

Each individual kind of soil is outlined and identified by a symbol on the soil map. All areas marked with the same symbol are the same kind of soil.

USING THE SOIL LEGEND TO FIND INTERPRETATIONS

The "Soil Legend" located at the front and back of the map sheets in the published soil survey and the index to soil interpretations in this Supplement can be used to find the soil properties and interpretations applicable to a kind of soil. The "Soil Legend" is an alphabetical list of all the symbols that appear on the soil map.

The following is an example of how to go from the soil map to the interpretations. If you are interested in an area of land mapped Pf, the first step is to go from the soil map to the "Soil Legend" and find the name of the soil that is shown by the symbol Pf. This soil is Plummer fine sand. The second step is to turn to the interpretations for the Plummer series which are arranged alphabetically. The page number for each soil series is shown in the Table of Contents.

PREPARING INTERPRETIVE MAPS

Individual maps showing the potential of soils for various uses can be developed by using the soil map and the interpretations. Potentials can be shown visually by color coding soil maps or transparent overlays to point up the potential of the soils for a particular use. A map or overlay can be made in this manner for each of the land uses rated. Once the interpretive map is complete, the patterns of soil potentials are readily apparent.

USE AND EXPLANATION OF SOIL PROPERTIES AND INTERPRETATIONS FOR SOILS
IN SEMINOLE COUNTY

The physical and chemical properties of each soil and interpretations for selected uses are provided. Included are: a brief description of the soil, estimated soil properties, interpretations of the soil as to its potential, its limitations, and the necessary practices to obtain its potential for selected land uses.

The interpretations will not eliminate the need for on-site sampling, testing, and study of specific sites for design and construction of engineering works and various uses. Estimated soil properties and interpretations should be used primarily to plan more detailed field investigations to determine the conditions of the soil at the proposed site for the intended use.

When the interpretations are used in connection with delineated soil areas on a soil map, the information pertains to the dominant soil for which the soil area is named. Other soils, too small in area to delineate, may occur within the soil map area. The interpretations ordinarily do not apply to the included soils. For example, areas mapped as Lakewood sand, 0 to 5 percent slopes (LdB) may include small unmappable areas of Pomello, Blanton, and St. Lucie soils. Each of these soils make up not more than 5 percent of any area mapped as Lakewood sand. The estimated soil properties and interpretations for LdB apply only to the Lakewood sand part of the delineated soil area, and not to the entire soil area, although some

of the properties and interpretations of these included soils are similar.

BRIEF SOIL DESCRIPTION

Each page containing soil properties and interpretations begins with a brief description of the soil. This brief description gives sufficient information for the user to get a mental picture of the soil, group its major features, and provides a landscape setting. The map symbol is shown at the top of the sheet with the soil name below it.

For a more complete description of the soils, see the published Soil Survey of Seminole County.

ESTIMATED SOIL PROPERTIES

The estimated soil properties are given for typical named soils. These estimates are based on test data and experience with similar soils in other counties in Florida. Following are explanations of items under the "ESTIMATED SOIL PROPERTIES."

Depth (In.) - The depth in inches of the major soil horizons that have similar properties are given.

USDA Texture - The USDA texture is based on the relative amounts of sand, silt, and clay in a soil, giving rise to textural classes such as sand, sandy loam, loam, clay loam, and clay. (USDA Handbook No. 18, SOIL SURVEY MANUAL).

Unified Classification - In the Unified System, soils are classified according to particle size distribution, plasticity, liquid limit, and organic matter. Soils are grouped in 15 classes. There are eight classes of coarse-grained soils, identified as GW, GP, GM, GC, SW, SP, SM, and SC; six classes of fine-grained soils, identified as ML, CL, OL, MH, CH, and OH; and one class of highly organic soils identified as Pt. Soils on the borderline between two classes are designated by symbols for both classes; for example, SP-SM.

AASHTO Classification - The AASHTO system is used to classify soils according to those properties that affect use in highway construction and maintenance. In this system, a soil is placed in one of seven basic groups ranging from A-1 through A-7 on the basis of grain-size distribution, liquid limit, and plasticity index. In group A-1 are gravelly soils of high bearing strength, or the best soils for subgrade (foundation). At the other extreme, in group A-7, are clay soils that have low strength when wet and that are the poorest soils for subgrade. The A-1, A-2, and A-7 groups can be further divided as follows: A-1-a, A-1-b, A-2-4, A-2-5, A-2-6, A-2-7, A-7-5, and A-7-6.

Fraction Greater than 3 Inches (Pct.) - Soils in Seminole County do not have material this coarse, with the possible exception of some of the soils in the Sandy alluvial land (Sn) mapping unit.

Percentage of Material Less than 3 Inches Passing Sieve No. - The measured or estimated percentages of materials passing the num-

bers 4, 10, 40, and 200 sieves are given for each major horizon. The percent passing the 200 sieve approximates the amount of silt and clay, but does include some very fine sand. A range is listed because of the variability for a given soil.

Liquid Limit and Plasticity Index - These indicate the effect of water on the strength and consistence of soil material. As the moisture content of a clayey soil is increased from a dry state, the material changes from a semisolid to a plastic state. If the moisture content is further increased, the material changes from a plastic to a liquid state. The plastic limit is the moisture content at which the soil material changes from the semisolid to plastic state; and the liquid limit from a plastic to a liquid state. The plasticity index is the numerical difference between the liquid limit and the plastic limit. It indicates the range of moisture content within which a soil material is plastic.

Permeability (In./Hr.) - That quality of a soil that enables it to transmit water or air. Values listed are estimates of the range in rate and time it takes for downward movement of water in the major soil layers when saturated, but allowed to drain freely. The estimates are based on soil texture, soil structure, available data on permeability and infiltration tests, and drainage observations of the water movement through soils. On a given soil, percolation through the surface layer varies according to land use and management as well as with initial

moisture content. The permeability is shown in inches per hour. For example, in a soil that has a permeability rate of 6.0 inches per hour in 3 hours free water would move downward a distance of (3x6") 18 inches.

Available Water Capacity (In./In.) - The ability of soils to hold water for plant use. The available water capacity is given in inches per inch of soil for the major horizons. It is commonly defined as the difference between field capacity (1/3 atmosphere) and the wilting percentage (15 atmospheres) times bulk density times the thickness in inches of the soil. The water retention by soil is related to the particle size and to the arrangement and size of soil pores. Fine-textured soils tend to have higher water retention due to small pores than do sandy soils with large pores. Estimates of the available water capacity for soils with normally high water tables may appear meaningless until one considers the possibility of artificial drainage or the natural lowering of the water table during dry seasons, or late summer or fall. Soils of the same series vary from place to place. Therefore, values can deviate considerably from those listed. The available water capacity is expressed in inches per inch. For example, in a soil that has an available water capacity of 0.10 in 1 inch of soil, there would be 0.1 inch of water available for plant growth, and in 24 inches of soil (0.1 x 24") 2.4 inches available.

Soil Reaction - Is the degree of acidity or alkalinity of a soil.

It is expressed in pH -- the logarithm of the reciprocal of the H-ion concentration. A soil that tests to pH 7.0 is precisely neutral in reaction because it is neither acid nor alkaline. In words, the degrees of acidity or alkalinity are expressed thus:

	pH
Extremely acid	Below 4.5
Very strongly acid	4.5 to 5.0
Strongly acid	5.1 to 5.5
Medium acid	5.6 to 6.0
Slightly acid	6.1 to 6.5
Neutral	6.6 to 7.3
Mildly alkaline	7.4 to 7.8
Moderately alkaline	7.9 to 8.4
Strongly alkaline	8.5 to 9.0
Very strongly alkaline	9.1 and higher

Salinity (mmhos/cm) - The salinity is expressed in terms of the electrical conductivity of a saturation extract in millimhos per centimeter at 25° centigrade. The following shows the response of plants associated with different ranges of electrical conductivity of saturation extracts of soils.

Electrical conductivity of saturation extract mmho./cm. at 25° C	Plant response
0-2	Salinity effects usually negligible.
2-4	Yield of very salt-sensitive crops may be restricted.

4-8	Yield of salt sensitive crops restricted.
8-16	Only salt-tolerant crops yield satisfactorily.
>16	Only a few very salt-tolerant crops yield satisfactorily

If salinity is zero or no problem for growing crops, a dash is shown on the sheet. Under normal conditions, soils in Seminole County do not exhibit a salinity problem.

Shrink-swell Potential - Is the relative change in volume to be expected of soil material with changes in moisture content; that is, the extent to which the soil shrinks as it dries out or swells when it gets wet. Extent of shrinking and swelling is influenced by the amount and kind of clay in the soil. Shrinking and swelling of soils cause much damage to building foundations, roads, and other structures. A high shrink-swell potential indicates a hazard to maintenance of structures built in, on, or with material having this rating.

Corrosivity - Steel - This refers to the potential for corrosion of uncoated steel pipe buried in the soil. The soils are rated as follows: LOW (noncorrosive or only slightly corrosive), MODERATE (moderately corrosive), and HIGH (severely corrosive). Corrosion of uncoated steel pipe is a physical-biochemical process converting iron into its ions. Soil moisture is needed to form solutions with soluble salts before the process can operate. The corrosivity is estimated

by electrical resistivity or resistance to flow of current, total acidity, soil drainage, and soil texture.

Corrosivity - Concrete - This refers to the potential for deterioration of concrete placed in soil materials. Deterioration is caused by a chemical reaction between the concrete (a base) and the soil solution (potential weak acid). Special cements and methods of manufacturing may be used to reduce rate of deterioration in soils of high corrosivity. Some of the soil properties that affect the rate of deterioration are soil texture and acidity, the amount of sodium or magnesium present in the soil singly or in combination, and amount of sodium chloride in the soil. The presence of large amounts of sodium chloride in the soil usually indicates that sea water has been present in the soil. Sea water contains sulphates which is one of the principal corrosive agents.

Erosion Factors (K and T) - A soil erodibility factor (K) and the soil-loss tolerance (T) are used in an equation that predicts the amount of soil loss resulting from rainfall erosion. The soil erodibility factor "K" is measure of the rate at which a soil will erode. Values are expressed as tons of soil loss per acre per unit of R (rainfall factor) from continuous fallow (three years or more) on a 9 percent slope, 73 feet long. Thus, the K factor reflects the rate that soil erodes when other factors affecting erosion are

constant. Soil properties that influence erodibility by water are: those that affect infiltration rate, movement of water through the soil, and water storage capacity; and those that resist dispersion, splashing, abrasion, and transporting forces from rainfall and runoff. Some of the soil properties that are most important are texture and organic matter of the surface layer, size and stability of structural aggregates in the surface layer, permeability of the subsoil, and depth to slowly permeable layers.

The soil-loss tolerance "T" sometimes called permissible soil loss, is the maximum rate of soil erosion that will permit a high level of crop productivity to be sustained economically and indefinitely. These rates are expressed in tons of soil loss per acre per year. Rates of 1 through 5 are used in the south, depending upon soil properties, soil depth, and prior erosion.

Wind Erodibility Groups - Soils that are subject to wind erosion are grouped into 8 groups according to their susceptibility to soil blowing. Soils that are permanently wet or that are deemed not to have a wind erosion hazard are shown by a dash on the soil properties interpretations sheet. Sandy soils are grouped into wind erodibility groups and are most susceptible to soil blowing, especially during dry periods and when wind velocities are high. Organic soils are normally wet, but they are also subject to soil blowing when

drained and cultivated if the soil surface is left bare during extreme dry periods and wind velocities are high.

Flooding - In Seminole County, flooding is defined as temporary covering of soil surface by water from any source, such as streams overflowing their banks, runoff from adjacent or surrounding slopes, or combinations of these. Shallow water standing above the soil surface in a more or less ponded condition for relatively long periods of time are excluded from the definition of flooding because water is more than a temporary covering; it is a water table above the soil surface rather than flooding.

Flooding hazard may be expressed by one of three general flood frequency classes -- none, rare, or common. Duration and time of year that the flooding occurs is given for those soils with common flood hazards. Not considered here, but nevertheless important, are velocity and depth of flood waters. The classes of flooding are defined as follows:

None -- No reasonable possibility of flooding.

Rare -- Flooding unlikely but possible under unusual weather conditions. No evidence of recent water deposited sediments on surface or within the pedon.

Common - Flooding is likely under usual weather conditions. Most pedons show evidence of recent water deposited sediments or scouring. The probability of recurring floods is great.

Duration refers to the length of time that the soils are flooded. These classes are as follows:

Brief -- 2 to 7 days.

Long - 7 days to 1 month.

Very long - More than 1 month.

The time of year that flooding would most likely occur is expressed in months, for example, June-October.

The economic and social consequences of improper land use of flood prone areas are serious. Problems begin when structures are located in flood prone areas. The initial development encourages additional construction and the installation of streets and utilities. The capacity of the floodway may be reduced by these kinds of development increasing the flood hazard. When flooding occurs, losses are not borne only by the property owner but by the community as well. The public is usually called upon to bear the cost of flood fighting, rehabilitation, and flood protection.

Dwellings, commercial buildings, and other high cost developments that are easily damaged by floods should not be located on flood prone soils. Sanitary facilities such as septic tank filter fields, sewage lagoons, and sanitary landfills built on flood prone soils present a health hazard. Roads and streets built on flood prone soils are likely to be

closed during floods and may require extensive maintenance or restoration after floods.

In agricultural areas the consequences of flooding are much less expensive, but nevertheless may present a hazard to the production of crops. The frequency, duration, and time of year that flooding occurs influences whether trees, pasture, or crops can be grown.

Trees and pasture can withstand more flooding than crops. Certain short season crops, however, can be grown successfully if the growing season is relatively flood free.

High Water Table - A high water table is defined as a zone of saturation at the highest average depth during the wettest season. It persists in the soil for more than a few days and occurs within 80 inches of the soil surface.

Most water tables occur within the soil and are measured from the surface of the soil down to the free-water level. In swamps, marshes, and depressional areas, however, the water table is above the surface of the soil much of the time and water table is measured from the surface of the water down to the soil surface.

Soils that have seasonal high water tables are classified according to depth to the water table, kind of water table, and time of year that the water table is highest.

The depth of the high water table from the soil surface is given in feet or half feet. The range in depth reflects the year-to-year variation in average highest depth. Depth to water table within the soil is recorded with the small number first, e.g., 1.5-2.5. Water table above the soil surface is used for marshes, swamps, and depressional areas and is recorded with the large number first with a +, e.g. + 1.0-0. Where a water table is below 6 feet or exists for less than one month, > 6 is shown under depth.

Three kinds of seasonal high water table are recognized within the soil: apparent, perched, and artesian.

Apparent water table is the level at which water stands in a freshly dug unlined borehole. It is influenced by the hydrostatic pressure of soil water and by pressure at greater depths penetrated by the borehole, water relations across impermeable layers, and other factors. In the absence of evidence that would permit greater specificity, therefore, the term apparent water table is used for the level at which water stands in an uncased borehole after adequate time for adjustment in the surrounding soil.

Perched water table is one that exists in the soil above an unsaturated zone. A water table may be inferred to be perched on the basis of general knowledge of the water levels of an area, the landscape position, the permeability

of soil layers, and from other evidence. To prove that a water table is perched, it is necessary to observe the water levels in cased wells placed above, in, and below the less permeable layer. If the water in the well above the less permeable layer is consistently higher than the other two, the water table is perched.

Artesian water table is one that exists under hydrostatic head beneath an impermeable layer; when the impermeable layer has been penetrated by a cased borehole, the water rises. The final level of the water in the cased borehole may then be characterized as an artesian water table.

The months that the water table normally persists at the average highest depth range is shown, for example, June-December.

A seasonal high water table is an important criterion in a number of engineering and biological uses of soils. Its depth and duration influences the potential and limitations of soils for septic tank absorption fields, shallow excavations, sanitary landfills, dwellings, and local roads and streets.

The water table also influences the growth of crops -- a water table that is near the surface during the growing season is detrimental to most crop plants. Growing plants, however, tend to lower the water table through transpiration.

A change in land use may drastically change the wetness of an area. For example, a change from trees to row crops changes the transpiration rate and may cause a wetter soil condition. Changing land use from cropland, pasture, or forest to urban areas with streets and houses covering a much larger area not only decreases the transpiration by vegetation but also causes increased runoff. A wetter soil may result.

Cemented Pan - This refers to a horizon or layer in the soil that is strongly cemented through the natural processes of soil formation. The depth to this kind of layer is shown in inches. The hardness of the pan is shown as RIPPABLE or HARD in the hardness column. If a soil does not have a cemented pan, a dash is shown in the depth column. (Rippable and hard are defined under "bedrock" below.) Weakly cemented soil horizons are common in some soils in Seminole County, but these are outside the definition of "Cemented pan".

Bedrock - This is solid rock beneath the soil. The depth to bedrock is shown in inches for soils with bedrock within 72 inches of the soil surface. All other soils are shown as > 72. The hardness of the bedrock is shown as RIPPABLE or HARD. "Rippable" rock can be excavated using a single tooth ripping attachment mounted on a 200-300 horsepower

tractor. "Hard" rock requires blasting or use of excavators larger than 200-300 horsepower. All of the soils in Seminole County have bedrock at depths of more than 72 inches.

Subsidence - This refers to the lowering of the level of the soil surface. When water is removed and the water table is lowered in organic soils and some mineral soils with low strength, the soil will subside. Initially, or in the first few years, the subsidence is most pronounced or greatest. Due to insufficient data, the initial subsidence is not estimated. After initial subsidence, organic soils in Florida subside or oxidize at the rate of about 1 inch per year. Total subsidence is estimated in inches.

Hydrologic Group - Soils are grouped into four hydrologic soil groups, A through D. These groups are used mostly in watershed planning to estimate runoff from rainfall. Soil properties were considered that influence the minimum rate of infiltration obtained for a bare soil after prolonged wetting. These properties are: depth to seasonally high water table, intake rate and permeability after prolonged wetting, and depth to a layer or layers that slow or impede water movement.

Dual hydrologic groups are given for wet soils rated D in their natural condition that can be adequately drained. It is considered that drainage is feasible and practical and

that drainage improves the hydrologic group by at least two classes (from D to A or B). The first letter applies to the drained condition.

Hydrologic group A - (Low runoff potential). Soils that have high infiltration rates even when thoroughly wetted and a high rate of water transmission.

Hydrologic group B - (Moderately low runoff potential). Soils that have moderate infiltration rates when thoroughly wetted and a moderate rate of water transmission.

Hydrologic group C - (Moderately high runoff potential). Soils that have slow infiltration rates when thoroughly wetted and a slow rate of water transmission.

Hydrologic group D - (High runoff potential). Soils having very slow infiltration rates when thoroughly wetted and a very slow rate of water transmission.

SOIL POTENTIAL, LIMITATIONS, AND NECESSARY MEASURES TO REACH POTENTIAL FOR SELECTED USES OF SOILS

Each soil is rated as to its potential for certain land uses, its degree of limitation, and the major practices that need to be applied to realize its potential for a selected use.

Land Use

The soils are rated for 14 different land uses. In the following paragraphs, these land uses are given with a brief discussion of each.

Septic tank absorption fields - These are subsurface systems of

tile or perforated pipe that distribute effluent from a septic tank into natural soil. The soil material from a depth of 18 inches to 6 feet is evaluated in determining a soil's potential for septic tank absorption fields. The soil properties considered are those that affect both absorption of effluent and construction and operation of the system. Properties that affect absorption are permeability, depth to water table or rock, and susceptibility to flooding. Slope is a soil property that affects difficulty of layout and construction and also the risk of soil erosion, lateral seepage, and downslope flow of effluent. Subsidence can cause the tile or pipe to gradually come closer to the surface and to eventually be above ground surface.

Sanitary landfill (trench) - This is a method of disposing of

refuse in a dug trench. The waste is spread in thin layers, compacted, and covered with a layer of soil material usually at least 6 inches thick, generally with soil evacuated in digging the trench. When the trench is full, a final cover of soil material at least 2 feet thick is placed over the landfill. For some soils, reliable predictions as to its potential for sanitary landfill can be made to a depth of 10 or 15 feet, but in most instances

geologic investigations will be needed below a depth of about 6 feet. Soil properties that have the most significance on a soil's potential are wetness, flooding, or standing water, permeability, soil texture, and slope.

Dwellings without basements - Dwellings are considered to be buildings not more than three stories high that are supported by foundation footings placed in undisturbed soil. Soil properties that have the most significance on a soil's potential are flooding or standing water, wetness, shrink-swell potential, soil strength, subsidence, and slope.

Low commercial buildings - These are commercial buildings less than three stories high that are supported by foundation footings. These buildings may occur as groups of buildings with connecting walls as in shopping centers or as single detached buildings. Land forming operations in preparing sites for these kinds of buildings may result in removal of all vegetative cover and exposure of the surface soil and, in some places, even the subsoil. Soil properties that have the most significance on a soil's potential are flooding or standing water, soil erodibility and soil blowing, slope, wetness, shrink-swell potential, soil strength, and subsidence potential.

Local roads and streets - These are roads and streets that have an all-weather surface expected to carry automobile traffic all

year. They have a subgrade of underlying soil material; a base consisting of gravel, crushed rock, or soil material stabilized with lime or cement; and a flexible or rigid surface, commonly asphalt or concrete. These roads are graded to shed water and have ordinary provisions for drainage. They are built mainly from soil at hand, and most cuts and fills are less than 6 feet deep. Soil properties that have the most significance on a soil's potential are soil strength, shrink-swell potential, flooding or standing water, wetness, and slope.

Shallow excavations - These are the kinds of excavations that require excavating or trenching to a depth of less than 6 feet, as for example, excavations for pipelines, sewer lines, phone and power transmission lines, basements, open ditches, and cemeteries. Soil properties that have the most significance on a soil's potential are soil texture as related to sidewall stability and to support for digging equipment, wetness, and slope.

Active play areas - These are areas that are used intensively for recreation. These include playgrounds, athletic fields, or any areas that are subject to heavy foot traffic in association with outdoor recreation. Soil properties that have the most significance on a soil's potential are flooding, soil

texture in the upper foot of soil, wetness, slope, and permeability.

Passive play areas - These are areas used for outdoor recreation that are not subject to heavy foot traffic, or the foot traffic is relegated to certain areas or paths. Soil properties that have the most significance on a soil's potential are flooding or standing water, soil texture in the upper foot of soil, wetness, and slope.

Excavated ponds aquifer fed - These are bodies of water created by excavating pits or dugouts into a ground-water aquifer. Excluded are ponds fed by runoff and also embankment-type ponds where the depth of water impounded against the embankment exceeds three feet. The assumption is made that the pond is properly designed, located and constructed, and that the water is of good quality. Soil properties that have the most significance on a soil's potential are depth to water table, duration of water table, and permeability of ground water aquifer.

Lawn grasses and ornamental plants - These include the common grasses used for lawns in Seminole County and ornamental plants adapted to the local climatic conditions. Soil properties that have the most signifidance on a soil's potential are available water capacity, average organic matter content in the upper foot of soil, wetness, texture of surface layer, and slope.

Improved pastures - These include the common grasses and legumes.

used in Seminole County for improved pastures. Soil properties that have the most significance on a soil's potential are available water capacity, average organic matter content in the upper foot of soil, wetness, natural fertility, and slope.

Woodland - These are areas used for the commercial production of wood. The potential productivity is based on the site index. Site index is based on the average height of dominant pine trees at age 50. Some of the soil limitations are erosion hazard, equipment limitations, seedling mortality, and plant competition. Some of the soil properties that have a significant effect on the ability of a soil to grow trees are the effective depth of the root zone, available water capacity, thickness and texture of the surface layer, amount of organic matter, depth to fine-textured material, aeration of the soil and wetness.

Citrus - These include the common citrus fruits grown for commercial production in Seminole County. Soil properties that have the most significance on a soil's potential are wetness, available water capacity, flooding or standing water, natural fertility, and slope.

Specialized row crops - These include such crops as cabbage, carrots, celery, cucumbers, lettuce, snap beans, and any other specialized vegetable crops grown in Seminole County. Soil

properties that have the most significance on a soil's potential are average organic matter content in the upper foot of soil, wetness, flooding or standing water, natural fertility, and slope.

Soil Potential

Each soil is rated as to its potential for 14 selected land uses. For the purpose of this Supplement, "Soil potential" is defined as the ability of the soil to produce, yield, or support a given structure or activity expressed in economic, social or environmental units of value. The criteria used for rating soil potential includes the relative difficulty or cost of overcoming soil limitations, the continuing limitations after practices in general use in overcoming the limitations are installed, and the suitability of the soil relative to other soils in Seminole County.

In Seminole County, a five-class system of soil potentials is used. They are defined as follows:

Very High potential - Soil limitations are minor or are relatively easy to overcome; performance for the intended use is excellent. Soils rated as very high potential are the best in the county for the particular use.

High potential - Some soil limitations exist, but practices necessary to overcome limitations are available at reasonable cost; performance for the intended use is good.

Medium potential - Soil limitations exist that can be overcome with recommended practices, but limitations are mostly of a continuing nature requiring practices that have to be maintained, or the practices are more difficult or costly than average; performance for the intended use ranges from fair to good.

Low potential - Serious soil limitations exist that are difficult to overcome and the practices necessary to overcome the limitations are relatively costly compared to those required for soils with higher potential; necessary practices may involve environmental values and considerations; performance for the intended use is poor or unreliable.

Very Low potential - Very serious soil limitations exist that are most difficult to overcome; initial cost of the practices and maintenance cost are very high compared to those for soils with high potential; environmental values are usually depreciated; performance for the intended use is inadequate or below acceptable standards.

Soil Limitations

Soil limitations are given for the 14 selected land uses.

Soils are rated as to their limitations as follows: Slight - soil properties generally favorable; Moderate - soil properties moderately

favorable; and Severe - soil properties unfavorable. The soil limitations are restrictive features or features that can adversely affect a particular use. Key phrases are shown which identify the specific kinds of soil limitations. A list of key phrases used and their explanation or definition follows:

<u>KEY PHRASE</u>	<u>EXPLANATION</u>
CLAYEY	Soil slippery and sticky when wet and slow to dry.
CUTBANKS CAVE-IN	Walls of cuts are unstable. The soil sloughs easily.
DEEP TO WATER	Deep to permanent water table during dry seasons.
DURATION HIGH WATER TABLE	Water table high for less than 6 months in most years.
EQUIPMENT LIMITATIONS	Reflects limitations in the use of equipment for managing or harvesting a tree crop.
DENSE VEGETATION	Thick natural plant growth that is difficult and costly to clear.
ERODES EASILY	Water erodes soil easily.
EROSION HAZARD	Potential severe erosion problem in woodland following cutting operations or in areas where the soil is exposed.

FLOODS	Soil temporarily flooded by stream overflow from adjacent slopes.
LOOSE SAND	Soil is soft and loose and lacks structural aggregates.
LOW NATURAL FERTILITY	Soil rather infertile and low in essential nutrients for plant growth.
LOW ORGANIC MATTER	Average organic matter content in the upper foot of soil less than 1.5 percent.
LOW SOIL REACTION	Phrase used only in organic soils (Histosols) with pH less than 4.5; the soils require large amounts of lime to raise the pH.
LOW STRENGTH	The soil has inadequate strength to support loads.
NO WATER	Too deep to ground water.
PERCS SLOWLY	Water moves through the soil slowly; affecting the specified use.
PLANT COMPETITION	A severe hazard from unwanted plants that prevent adequate natural or artificial regeneration without site preparation and maintenance treatments and that also compete with desirable trees.

SANDY	Sand texture that has structural aggregates but soil subject to becoming soft and loose with intensive use.
SEEDLING MORTALITY	In woodland plantings or seedings during the first two growing seasons, unsatisfactory survival is likely on more than 50 percent of the area.
SEEPAGE	Water moves through the soil so quickly that it affects the specified use.
SHRINK-SWELL	The soil expands on wetting and shrinks on drying, which may cause damage to roads, dams, building foundations or other structures.
SLOPE	Slope too great.
SLOW REFILL	Ponds fill slowly because the permeability of the soil is restricted.
SOIL BLOWING	Soil easily moved and deposited by wind.
STANDING WATER	Shallow water standing above the soil surface (ponded) for relatively long periods of time.
SUBSIDENCE	Settlement of organic soils or of soils containing semifluid layers.

VERY LOW AVAILABLE
WATER CAPACITY

Less than 4 inches of available water in the upper 80 inches of soil; plants on these soils frequently suffer from lack of moisture unless irrigated.

VERY LOW ORGANIC
MATTER CONTENT

Average organic matter content in the upper foot of soil less than 0.8 percent.

WETNESS

Soil wet during period of use.

WINDTHROW HAZARD

Potential severe hazard of trees being blown over by high winds during storms.

Necessary Measures to Reach Potential

The necessary practices to obtain potential are shown for the 14 selected land uses. The list of practices is not inclusive but covers the major and most obvious ones. Listing of a practice does not necessarily condone its use. State and local regulations should be consulted prior to installation. Practices are identified and explained below in a general way and are not intended to imply design criteria.

PRACTICE

EXPLAINED

ADEQUATE LIME

Apply the necessary amount of agricultural lime to raise the pH level of the soil to the most desirable level for the growth of plants.

ADEQUATE SURFACE DRAINAGE	Ditches or any other means to remove excess water from the surface or upper foot of soil.
ADD WATER DURING DRY PERIODS	Apply water from any available source. This is not a practical solution unless the pond has been lined or sealed.
BEDDING	A partial method of controlling excess water for the growth of citrus using regularly spaced shallow ditches and beds.
CLEAR NATIVE VEGETATION	Dense vegetation cleared by whatever practical means so that improved pasture grasses can be planted and maintained.
CONSTRUCT ABOVE GROUND WALKS	Walkways built of appropriate materials to carry foot traffic above ground level to help protect and preserve ecosystems.
CONTROL FLOOD WATER (Control Flooding)	Protect area from accumulation of waters above the soil surface, such as by use of dikes.
CONTROL SOIL BLOWING	Control the movement of soil material caused by wind action by such practices as wind-break plantings, good vegetative cover, keeping the surface moist, paving, etc.

DESIGN BUILDING
TO FIT SLOPE

Use good design and place buildings
in harmony with the landscape.

FILL AREA

Raise the surface level of the land to the
desired level by filling area with suitable
soil material.

GOOD MANAGEMENT

For growing grasses, crops, citrus, trees,
or any plants, use recommended practices for
obtaining and maintaining good production,
and maintaining and protecting the soil.
Recommended management practices will vary
with the product being grown and the kind
of soil such as: the fertilization program,
erosion control measures to use, whether to
lime, the amount of supplemental irrigation
water to apply and when, and cultivating and
harvesting methods.

INCREASE STRUCTURAL
STRENGTH IN
FOUNDATION

By recommended building methods, insure that
additional strength is added to withstand
large amounts of stress.

INCREASE AREA FOR
FOUNDATIONS AND
FOOTINGS

By recommended building methods increase the
area to the necessary level to provide ade-
quate strength and support for the building.

LAND FORMING	Reduce slope gradient by cutting and filling.
LAND SMOOTHING	Rearrangement of soil materials by cutting and filling to form a level or nearly level surface.
MAINTAIN EVEN MOISTURE CONTENT	Prevent soil from drying out by whatever appropriate or feasible method so as to prevent the soil from shrinking.
MOUNDING	Filling the area for the absorption field with suitable soil material to the level above the water table necessary to meet local and State requirements.
NONE NEEDED	No practices needed for the applicable land use.
NO PRACTICAL PRACTICES AVAILABLE	No known feasible or practical practices available.
PAVING (Hard Surface)	Covering of the surface with asphalt, concrete, or other similar materials.
PLANT ON BEDS	Plant tree seedlings on beds to keep roots of seedlings above the water table to aid in establishment.

REMOVE AND REPLACE WITH SUITABLE MATERIAL	Remove undesirable soil material and replace with suitable soil material.
RESTRICT USE DURING FLOODING	Restrict use of the area while the area is covered with flood waters.
SEALING OR LINING	Seal or line the bottom of the excavation with the appropriate materials to prevent the downward movement of water or seal or line the side of the excavated trench with the appropriate materials to prevent the lateral movement of water.
SHORING	Construct walls along sides of excavated trenches to prevent soil from sloughing.
SPECIAL EQUIPMENT	Digging equipment needed that can traverse soft and wet soils of low strength.
STABILIZE SIDESLOPES	By whatever practical means stabilize sideslopes of excavated ponds.
SUBSURFACE IRRIGATION	Provide water at below ground level to crops and grasses by manipulating and controlling the water table.

SUITABLE TOPSOIL AND OTHER AMENDMENTS	Add suitable topsoil or appropriate soil amendments to help facilitate stabilization of the soil surface.
SURFACE STABILIZATION	Stabilize the surface by whatever appropriate means so that vehicles can move into and out of the area.
USE CALCIUM TOLERANT ORNAMENTALS OR REDUCE SOIL REACTION	Use ornamentals that can grow on soils high in calcium or apply the appropriate chemicals to reduce the soil reaction or pH to the desired level.
WATER CONTROL	Regulate the water table according to the need of the land use by canals, ditches, pumping, tile, or any other appropriate method.

SOILS SHOWN ACCORDING TO THEIR POTENTIAL FOR SELECTED LAND USES

In tables 1 through 14, the soils are arrayed according to their potential for the specific land use. Soils are grouped and arrayed from very high to very low potential. The numerical rankings were determined by assigning positive points to those soil properties that affect a particular use, multiplying each point by a weighting factor, and then summing the products. The weighting factor is a variable number or device used to maneuver or weight the properties so that a soil with all favorable properties will have a numerical ranking of 100. Properties considered favorable were assigned a point value of 5, those less favorable a point value of 4, 3, 2, or 1, and those considered most unfavorable a value of 0. For example, in local roads and streets, the following properties were used: soil strength, shrink-swell potential, flooding or standing water, wetness, and slope. A soil such as Lakeland fine sand, 0 to 5 percent slopes that has good strength (5 positive points x weighting factor of 5 = 25 points), low shrink-swell potential (5 positive points x weighting factor of 5 = 25 points), not subject to flooding (5 positive points x weighting factor of 4 = 20 points), not wet (5 positive points x weighting factor of 4 = 20 points), and gentle slopes (5 positive points x weighting factor of 2 = 10 points) has a numerical ranking or point value of 100, the highest potential numerical ranking. The highest point totals were assigned to those properties that would have the most effect on the particular land use. In local roads and streets, soil strength and shrink-swell potential were considered of

most importance, flooding and wetness of slightly less importance, and slope of least importance. Theoretically, a soil could have a potential as low as 0 or as high as 100, but for all the land uses considered, most soils in Seminole County came out with a numerical ranking of more than 0. For some land uses, there were some soils that had a numerical ranking of 100, and for some land uses, there were not any soils that had a numerical ranking as high as 100.

The percent of the county that each soil comprises is also shown in the tables. This will enable users to quickly calculate the extent of the soils with the best potential for a particular use.

The last column in the table refers you to the page that has the properties and interpretations for a particular soil.

SOIL PROPERTIES AND INTERPRETATION TABLES

SOIL PROPERTIES AND INTERPRETATIONS

MAP SYMBOL: BfB

MAP SYMBOL: BfB

SOIL NAME: Blanton fine sand, high, 0 to 5 percent slopes

This soil is deep and is somewhat excessively drained to well drained. It is on high, gently sloping ridges. The surface layer is generally dark-gray, loose fine sand about 6 inches thick, but it is gray in some places. Below the surface layer is light-gray to grayish-brown, loose fine sand mottled with light gray, white, and yellow. The total thickness of the fine sand over finer textured material is more than 40 inches. In some places sandy clay loam is at a depth of 60 inches or more.

SOIL PROPERTIES AND INTERPRETATIONS

MAP SYMBOL: BfC

MAP SYMBOL: BfC

SOIL NAME: Blanton fine sand, high, 5 to 8 percent slopes

This is a deep, sandy soil that is well drained or somewhat excessively drained. It is on high, undulating ridges. The surface layer is typically dark-gray, loose fine sand about 6 inches thick, but it is gray in some places. Below the surface layer is light-gray to grayish-brown, loose fine sand that is mottled with light gray, white and yellow. The total thickness of the fine sand over finer textured material is more than 40 inches. In places sandy clay loam is at a depth of 60 to 100 inches.

SOIL PROPERTIES AND INTERPRETATIONS

MAP SYMBOL: BfD

MAP SYMBOL: BfD

SOIL NAME: Blanton fine sand, high, 8 to 12 percent slopes

This is a deep, sandy soil that is well drained or somewhat excessively drained. It occupies high, moderately steep areas. The surface layer is gray, loose fine sand about 6 inches thick. Below the surface layer is light-gray to grayish-brown, loose fine sand mottled with light gray, white and yellow. The thickness of the fine sand over finer textured material is more than 40 inches. In many places sandy clay loam underlies this soil at a depth of 60 to 100 inches.

MAP SYMBOL: Bo

SOIL NAME: Borrow Pits

Borrow pits are manmade excavations from which the soil material and the underlying coarse material have been removed for use in construction. The material removed is used for raising the level of sites for buildings, for road construction and repairs, and for cement mixtures. The areas vary in size and shape, but they are generally small and occupy only a minor acreage throughout the county.

SOIL PROPERTIES AND INTERPRETATIONS

MAP SYMBOL: Bt

MAP SYMBOL: Bt

SOIL NAME: Brighton, Istokpoga, and Okeechobee soils

This undifferentiated unit consists of organic soils that are too wet or have too dense a cover of vegetation to be studied and separated on the map. The areas are dominated by Brighton, Istokpoga, and Okeechobee soils, but they vary in composition throughout the county. One or more of these soils makes up at least 80 percent of any area. These soils are on low grassy flats and in wooded depressions, and they are covered by water most of the year, except in periods of extreme drought. The cover of plants consists of water-tolerant grasses and hardwoods, black pine, cypress, cabbage-palm, and shrubs.

SOIL PROPERTIES AND INTERPRETATIONS

MAP SYMBOL: Ch

MAP SYMBOL: Ch

SOIL NAME: Charlotte fine sand

This is the only Charlotte soil mapped in the county. It is a deep, poorly drained, sandy soil on low, broad flats. The surface layer is generally black, loose fine sand about 4 inches thick, but it is dark gray in some places. The material below the surface layer is yellow to brown, and it has mottles that vary in degree and intensity.

MAP SYMBOL: De

SOIL NAME: Delray fine sand

This is a very poorly drained, deep, sandy soil of the depressions. Its surface layer is black, friable fine sand that is about 20 inches thick in most places but is thinner in some areas. Below the surface layer is gray to light grayish-brown fine sand that contains a few fine mottles of dark gray and brown. The sandy material is commonly more than 42 inches thick, but clayey material is a depth of 30 to 42 inches in some places.

SOIL PROPERTIES AND INTERPRETATIONS

MAP SYMBOL: Ff

MAP SYMBOL: Ff

SOIL NAME: Felda fine sand

This is the only Felda soil mapped in the county. It is a deep, slightly acid to neutral, poorly drained soil on flood plains. The surface layer is generally very dark gray, very friable fine sand about 5 inches thick, but it is dark gray or black in places. Immediately below the surface layer is loose fine sand.

The subsoil is generally dark-gray, slightly sticky fine sandy clay loam that contains a few fine mottles of brownish yellow. The texture is fine sandy loam, however, in some places. In some areas the lower part of the subsoil contains streaks where calcareous material occurs. The substratum in most places is light-gray, friable sandy loam that contains a few, fine, yellow mottles, but the texture is fine sandy clay loam in some places.

SOIL PROPERTIES AND INTERPRETATIONS

MAP SYMBOL: Im

MAP SYMBOL: Im

SOIL NAME: Immokalee fine sand

This soil is deep, somewhat poorly drained, and strongly acid or very strongly acid. It is nearly level and is generally in low areas. The surface layer is black to gray fine sand that has weak granular structure and is about 5 inches thick. Below the surface layer is gray or light-gray, loose fine sand about 25 to 42 inches thick. The third layer is weakly cemented and is black because it is stained with organic matter. It ranges from soft to slightly hard.

MAP SYMBOL: Lo

SOIL NAME: Leon sand

This is a moderately wet soil, mainly in an area south of Oviedo. The surface layer is gray to black, loose sand about 3 inches thick. The second layer is gray to light-gray, loose sand and is at a depth of 4 to 23 inches. The third layer is black to very dark brown sand and is at a depth of 23 to 27 inches. It ranges from 4 to 12 inches in thickness and is weakly cemented to firm. Below the third layer, at a depth of about 35 inches, is brown, loose sand.

SOIL PROPERTIES AND INTERPRETATIONS

MAP SYMBOL: Ma

MAP SYMBOL: Ma

SOIL NAME: Made land

Consists of clayey or sandy material, or both, that has been reworked by soil-moving equipment. Some areas consist of raw geologic material, and some areas contain a large amount of organic matter. The areas have been built up by using soil material that was either brought in by truck or was dredged in. Smoothing or leveling has made them suitable for use as building sites, causeways, recreational areas, or other uses. Made land occurs throughout the county in urban areas or close to urban areas.

Because of the wide range of soil characteristics, most of them unfavorable, this land type is generally not suited to cultivated crops. The areas that have been made from sandy soil material, that have a moderately high content of organic matter, that have been leveled, and that are as much as 30 inches above the highest point reached by the water table can be used for improved pasture or to grow citrus trees and pine trees. The dredged material is likely to be highly washed and is poorly suited to plants. Where the slopes are short and steep, the soil material is erodible and measures for controlling erosion are needed.

SOIL NAME: Manatee loamy fine sand

This is a wet, gray, mottled soil in depressions. Its surface layer is black loamy fine sand about 12 inches thick. Below the surface layer is dark-gray sandy clay loam that is mottled with brown and yellow and is about 20 inches thick. The subsoil is gray or dark-gray, calcareous clay-mottled with brown and white. This soil is more than 42 inches thick.

SOIL PROPERTIES AND INTERPRETATIONS

MAP SYMBOL: Md

MAP SYMBOL: Md

SOIL NAME: Manatee-Delray complex, overflow

About 60 percent of this complex consists of very poorly drained Manatee soils, and about 40 percent of very poorly drained Delray soils. These soils are on the flood plain of the St. Johns River; they are so intricately mixed that it was impractical to separate them on the map. The texture of their surface layer is fine sand or mucky fine sand. The Manatee soils are shallower over loamy material than the Delray soils; loamy material is at a depth of less than 30 inches in the Manatee soils but is at a depth of more than 30 inches in the Delray soils. A representative profile of the Delray soils is described under the Delray series.

SOIL PROPERTIES AND INTERPRETATIONS

MAP SYMBOL: On

MAP SYMBOL: On

SOIL NAME: Ona fine sand

This is the only Ona soil mapped in this county. It is a somewhat poorly drained, deep, very strongly acid fine sand in small nearly level areas in the eastern and central parts of the county. In most places the surface layer is black fine sand about 6 inches thick. The second layer is generally dark reddish-brown fine sand about 12 inches thick, and it is underlain by light yellowish-brown fine sand. This soil is more than 42 inches thick.

SOIL PROPERTIES AND INTERPRETATIONS

MAP SYMBOL: PmB

MAP SYMBOL: PmB

SOIL NAME: Pomello fine sand, 0 to 5 percent slopes

This is the only Pomello soil mapped in the county. It is slightly wet and is very strongly acid. The surface layer is light-gray fine sand about 4 inches thick and the second layer is white fine sand about 36 inches thick. The third layer is dark reddish-brown fine sand that is stained with organic matter and is about 10 inches thick. The fourth layer is very pale brown fine sand more than 30 inches thick. The total thickness of the profile is more than 12 inches.

SOIL PROPERTIES AND INTERPRETATIONS

MAP SYMBOL: Rh

MAP SYMBOL: Rh

SOIL NAME: Rutlege fine sand, high

This is a deep, nearly level, poorly drained soil that is very strongly acid. It occurs throughout the western and central parts of the county in positions higher than those occupied by Rutlege fine sand. This soil is generally in narrow bands that separate well-drained soils in higher positions from areas of wet or very wet soils below.

The surface layer is generally black fine sand about 20 inches thick, but the thickness ranges from 8 to 30 inches. Below the surface layer is light-gray or gray fine sand that is more than 30 inches thick and contains a few faint mottles of very dark grayish brown. In places a discontinuous layer of soft iron concretions is at a depth of 42 inches or more.

SOIL PROPERTIES AND INTERPRETATIONS

MAP SYMBOL: Sa

MAP SYMBOL: Sa

SOIL NAME: St. Johns fine sand

This soil is somewhat poorly drained or poorly drained and is strongly acid. It is mainly in the flatwoods area of the county. The surface layer is black fine sand about 12 inches thick, and the second layer is light-gray, loose fine sand about 18 inches thick. Below the second layer is black, weakly cemented fine sand that is stained with organic matter and is about 5 to 18 inches thick. The fourth layer is dark-brown to pale-brown, loose fine sand that is at a depth of 34 to 46 inches.

SOIL PROPERTIES AND INTERPRETATIONS

MAP SYMBOL: SFB

MAP SYMBOL: SFB

SOIL NAME: St. Lucie fine sand, 0 to 5 percent slopes

This is the only St. Lucie soil mapped in the county. It is a deep, excessively drained, sandy soil on low ridges. The surface layer is gray sand or fine sand about 3 inches thick. Below the surface layer is white, loose sand that is droughty and is more than 30 inches thick. In some places yellow to yellowish-brown sand underlies the second layer. In other places a layer stained with organic matter is at a depth of more than 48 inches.

SOIL PROPERTIES AND INTERPRETATIONS

MAP SYMBOL: Sn

MAP SYMBOL: Sn

SOIL NAME: Sandy alluvial land

Sandy alluvial land is adjacent to streams and is subject to frequent overflow. It consists of sandy sediments, but the texture varies. Generally coarse sand is near the streams and fine sand has been deposited by backwater in the low areas away from the stream channel. The higher areas adjacent to deep channels are better drained and are generally more brownish and yellowish than the low areas, which are more poorly drained and more grayish. Some of the wetter areas are also affected by seepage from adjacent soils. Many areas are sharply dissected by meandering stream channels.

SOIL PROPERTIES AND INTERPRETATIONS

MAP SYMBOL: Sw

MAP SYMBOL: Sw

SOIL NAME: Swamp

Swamp is a land type covered by dense vegetation and by water most of the year, except during extended dry periods. It occurs throughout the county along drainageways, along poorly defined streams, in depressions that have no outlets, and along large bay heads.

Not much alluvial soil material is deposited in the areas along streams, because the floodwaters move slowly. Small deposits of soil material may wash onto the edges of bay heads and depressions from adjacent higher areas. This land type includes mineral soils and organic soils that range from strongly acid to neutral in reaction.

SOIL PROPERTIES AND INTERPRETATIONS

MAP SYMBOL: Tc

MAP SYMBOL: Tc

SOIL NAME: Terra Ceia muck

This is the only Terra Ceia soil mapped in the county. It is very poorly drained and is covered by water most of the year. The surface layer is black, well-decomposed, slightly acid to neutral muck about 20 inches thick. Below the surface layer is light brownish-gray to dark-brown or gray sandy loam to sandy clay loam. In some places this layer is fine sand. In other places a layer of very dark brown, slightly decomposed felty peat, about 5 to 10 inches thick, lies just below the surface layer.

SOIL PROPERTIES AND INTERPRETATIONS

MAP SYMBOL: Wa

MAP SYMBOL: Wa

SOIL NAME: Wabasso fine sand

This is the only Wabasso soil mapped in the county. It is level or nearly level and is somewhat poorly drained. The areas are in the northern and eastern parts of the county. The surface layer is very dark gray fine sand about 7 inches thick. The second layer is gray, loose fine sand that is 7 to 20 inches thick. The third layer is very dark brown fine sand that is stained with organic matter and is 4 to 12 inches thick. It is at a depth of about 24 inches.

The first three layers are strongly acid. The fourth layer is brown, neutral fine sand and is at a depth of 26 to 36 inches. It is underlain by mottled brownish-yellow and gray fine sandy loam or fine sandy clay loam. This finer textured layer is at a depth of more than 30 inches but generally less than 42 inches.
